

# Two-Pass 3D Reconstruction for Line-of-Sight Audits at Crosswalks

Anonymous CVPR submission

Paper ID \*\*\*\*\*

## Abstract

001 We want to replay a real intersection in true 3D over time  
002 and ask a simple safety question: could this person at the  
003 curb actually see that approaching car. We build a 3D  
004 snapshot for each moment from eight synchronized cam-  
005 eras. With that finished world we compute from a pedes-  
006 trian's eye to the vehicle and measure when and how much  
007 it was visible and what blocked it.

## 008 1. Introduction

009 This project creates a complete, time-consistent 3D video  
010 of a traffic intersection from eight synchronized cameras to  
011 audit the line-of-sight between pedestrians and approach-  
012 ing vehicles [6]. A two-pass method first generates a 3D  
013 snapshot for each moment, then temporally fuses partial  
014 views of dynamic subjects into complete 3D models so  
015 that occluded geometry is recovered before safety analysis,  
016 extending multi-view reconstruction ideas popularized by  
017 neural radiance fields [6]. The final interactive 3D scene  
018 allows for precise ray-casting analysis to determine when  
019 a pedestrian's view of any vehicle travelling toward the in-  
020 tersection was obstructed, closing the gap between manual  
021 sight-distance checks and data-driven audits [1].

### 022 1.1. Problem Statement

023 At urban intersections, pedestrians at the curb often face  
024 blocked views of approaching vehicles due to occlusions  
025 like parked cars, poles, or other obstacles. This visibility is-  
026 sue creates a serious safety risk, impairing people's ability  
027 to judge traffic conditions before crossing and contributing  
028 to preventable accidents documented in intersection safety  
029 reviews [5]. In the United States alone, 7,388 pedestrians  
030 were killed in traffic crashes in 2021, with limited sight  
031 distance called out as a contributing factor in urban corri-  
032 dors [7].

### 033 1.2. Research Significance

034 Solving this matters for safer streets and better urban de-  
035 sign. By building time-consistent 3D models from multi-

camera data, this project audits line-of-sight (LoS), a core  
principle of transportation safety [2], between pedestrians  
and vehicles, pinpointing exact blockers that hide dan-  
gers. These insights can drive real fixes, such as remov-  
ing or redesigning obstacles, adding signs, or implement-  
ing smart traffic controls. Broader impacts include fewer  
pedestrian-vehicle crashes, improved transportation plan-  
ning, and more accessible cities. Quantitatively, enhanced  
LoS could reduce accident rates, cut costs in healthcare and  
insurance, and minimize disruptions in daily mobility, lead-  
ing to more resilient and people-centered urban environ-  
ments while keeping documentation compatible with trans-  
portation design guidance [1].

## 048 2. Proposal

### 049 2.1. Related Work

050 Today, most visibility or safety audits at intersections are  
051 done manually or in 2D. City planners, engineers, or re-  
052 searchers usually look at 2D video footage, static camera  
053 views, or CAD maps to perform LOS audits [1].  
054 The issue is that real-world visibility is 3D and dynamic:  
055 people and vehicles move, change orientation, and are par-  
056 tially hidden by other moving or static objects. Traditional  
057 methods cannot capture these occlusions correctly, espe-  
058 cially when multiple cameras or viewpoints are involved,  
059 so planners often miss hidden hazards.  
060

### 061 2.2. Proposed Method

062 We will build a 3D Line-of-Sight (LoS) Visibility Audit  
063 system that reconstructs intersections in full 3D and tests  
064 whether pedestrians at the curb can actually see approach-  
065 ing vehicles (and vice versa).  
066 Use multi-view video data (8 synchronized cameras) to  
067 reconstruct a metric 3D model of the scene using Fast-  
068 VGGT [10] for per-timestamp depth and pose estimation.  
069 Apply a two-pass reconstruction method: the first pass  
070 builds per-timestamp 3D scenes and the second pass fuses  
071 later frames of each moving subject to create complete 3D  
072 models that fill in missing sides. To link the same sub-  
073 jects across time we use YOLO [9] (object detection) and

|     |                                                                   |     |
|-----|-------------------------------------------------------------------|-----|
| 074 | SAM [4] (segmentation and tracking) for object detection          | 125 |
| 075 | and segmentation.                                                 | 126 |
| 076 | Perform line-of-sight testing by casting rays from a pedes-       | 127 |
| 077 | trian’s eye point toward intersecting vehicles in the 3D          | 128 |
| 078 | scene, checking for occlusions from static and dynamic ob-        | 129 |
| 079 | jects. This will allow us to produce a LOS audit, showing         | 130 |
| 080 | exactly where and when visibility is lost and which design        | 131 |
| 081 | elements or parked vehicles cause the issue.                      | 132 |
| 082 | The system outputs interactive reports that match the cam-        | 133 |
| 083 | era views used in safety studies while attaching 3D overlays      | 134 |
| 084 | that pinpoint root causes of occlusion.                           | 135 |
| 085 | <b>2.3. Why it works?</b>                                         | 136 |
| 086 | The system succeeds because the two-pass reconstruction           | 137 |
| 087 | gives us more complete and realistic 3D geometry than tra-        | 138 |
| 088 | ditional single-pass or 2D methods. By fusing views and           | 139 |
| 089 | frames, we recover hidden sides of vehicles and pedestri-         | 140 |
| 090 | ans, which is essential for accurate visibility testing. Proven   |     |
| 091 | tools like Fast-VGGT [10] (for 3D reconstruction), YOLO           |     |
| 092 | + SAM [4, 9] (for detection/segmentation), and ICP [3] (for       |     |
| 093 | temporal alignment) give reliable and reproducible results.       |     |
| 094 | In short, the method directly addresses the lack of full 3D,      |     |
| 095 | time-consistent visibility in current audits and leverages        |     |
| 096 | modern computer vision models to create a realistic, mea-         |     |
| 097 | surable, and interpretable audit system.                          |     |
| 098 | <b>3. Methodology</b>                                             |     |
| 099 | We begin by cleaning the footage, skipping black sync             |     |
| 100 | frames and choosing a short well lit window (15–30 seconds        |     |
| 101 | per scenario). We anchor scale with a simple scene prior          |     |
| 102 | such as crosswalk stripe spacing so distances are meaning-        |     |
| 103 | ful and consistent with roadway design drawings.                  |     |
| 104 | Pass one asks what we saw right now. The eight images             |     |
| 105 | at a time go to Fast-VGGT [10], which returns depth for           |     |
| 106 | each view and camera poses with reported $< 5$ cm RMSE            |     |
| 107 | on multi-view datasets. The slice mixes the road and the          |     |
| 108 | movers, so we separate them. YOLO [9] marks people,               |     |
| 109 | bikes, and vehicles at real-time rates ( 45 FPS on 640 px         |     |
| 110 | frames), and SAM [4] turns each box into a crisp mask. We         |     |
| 111 | split the slice into a static background and per-object point     |     |
| 112 | clouds. A simple 3D tracker assigns a stable identity to each     |     |
| 113 | subject using motion, proximity, and a compact appearance         |     |
| 114 | cue.                                                              |     |
| 115 | Pass two lets the future complete the past. For each tracked      |     |
| 116 | vehicle we recenter the masked points into the vehicle frame      |     |
| 117 | using its pose timeline. Short, robust alignment stitches the     |     |
| 118 | pieces into a single canonical car, leveraging ICP-style fit-     |     |
| 119 | ting [3] with a 2 cm convergence tolerance. Pedestrians are       |     |
| 120 | represented with a simpler non-rigid proxy, which is enough       |     |
| 121 | for visibility. We then replay the clip and place the com-        |     |
| 122 | pleted car into the early frames where only a bumper had          |     |
| 123 | been seen. Frame by frame the world becomes a consistent          |     |
| 124 | 3D video.                                                         |     |
|     | The line-of-sight audit is then a direct query. For a pedes-      | 125 |
|     | trian we set an eye point around fixed heights’ above the         | 126 |
|     | road to address diversity. We sample key points on each ap-       | 127 |
|     | proaching vehicle and cast rays through the scene at 1 cm         | 128 |
|     | step size. If a ray hits something first the target is not vis-   | 129 |
|     | ible. From these rays we read three values that matter for        | 130 |
|     | safety: when the vehicle first became visible, how much of        | 131 |
|     | it was visible over time, and how long it stayed hidden while     | 132 |
|     | approaching.                                                      | 133 |
|     | Feasibility is practical. A focused prototype fits in three       | 134 |
|     | weeks on a single cloud GPU. Week one delivers per-               | 135 |
|     | timestamp reconstruction, instance masks, tracking, and a         | 136 |
|     | viewer of the 3D slices. Week two delivers vehicle fusion         | 137 |
|     | across time, placement back into earlier frames, and week         | 138 |
|     | three integrates the LoS audit with initial quantitative mea-     | 139 |
|     | surements.                                                        | 140 |
|     | <b>4. Planned Experiments</b>                                     | 141 |
|     | <b>4.1. Data</b>                                                  | 142 |
|     | Dataset: StreetAware: A High-Resolution Synchronized              | 143 |

|     | We use sample sequences captured by four corner sensor            | 145 |
|     | pod (8 synchronized RGB cameras).                                 | 146 |
|     | <b>4.2. Evaluation Metrics</b>                                    | 147 |
|     | • <b>End-to-End Line-of-Sight (LoS) Accuracy</b>                  | 148 |
|     | Visibility score (0-1): fraction of the vehicle’s projected       | 149 |
|     | surface whose depth lies in front of the scene depth within       | 150 |
|     | $\pm 30$ cm. Clear $\geq 0.6$ Partial 0.1-0.6 Complete $\leq 0.1$ | 151 |
|     | Occluder Attribution: Top-1 accuracy for identifying the          | 152 |
|     | blocking object (parked car, pole/sign, moving vehicle,           | 153 |
|     | tree/foliage).                                                    | 154 |
|     | • <b>3D Completeness and Quality Metrics</b>                      | 155 |
|     | The 3D completeness and quality metrics assess the reli-          | 156 |
|     | ability of reconstructed geometry for LOS analysis. Voxel         | 157 |
|     | Occupancy Coverage (VOC) measures the percentage of               | 158 |
|     | occupied voxels within a 5 cm grid, indicating recon-             | 159 |
|     | struction density; and Multi-View Reprojection Consis-            | 160 |
|     | tency (MVRC) quantifies depth consistency across multi-           | 161 |
|     | ple views, also serving as a confidence filter [12].              | 162 |
|     | <b>4.3. Comparative Baselines</b>                                 | 163 |
|     | Backbones: FastVGGT (primary) vs PI3 (baseline for qual-          | 164 |
|     | ity/speed trade-off) [10, 11]                                     | 165 |
|     | Confidence Usage: With vs without MVRC-based masking              | 166 |
|     | to demonstrate robustness against noisy geometry.                 | 167 |
|     | 2D Control (No 3D): Simple image-plane line test between          | 168 |
|     | pedestrian and vehicle bounding boxes, labeling visible           | 169 |
|     | when no other box lies between, included to illustrate the        | 170 |
|     | necessity of 3D reasoning.                                        | 171 |

#### 4.4. Hypotheses and Experiments

Hypothesis: A Two-Pass, confidence-filtered 3D reconstruction (actor completion across time + MVRC masking) produces more accurate LoS decisions and occluder identification than single-pass or 2D heuristics on StreetAware multi-view scenes [8].

Experiments:

- **E1:** Establishes a baseline by fusing multi-view FastVGGT/PI3 outputs into a metric-scaled world point cloud and evaluating runtime and MVRC [10–12].
- **E2:** Performs two-pass actor completion using tracking, segmentation, and ICP-based fusion to enhance VOC and MVRC [3, 4, 9, 12].
- **E3:** Builds an integrated 3D scene video combining static background and dynamic actors for qualitative inspection.
- **E4:** Conducts the main LoS audit by casting rays from pedestrians to vehicles and evaluating visibility scores, benchmarking against the 2D control.
- **E5:** Tests robustness under small pose perturbations, comparing FastVGGT vs PI3, single-frame vs two-pass, and 3D vs 2D control approaches [10, 11].
